The Transition to Market-Based Monetary Policy: What Can China Learn from the European Experience?

Abstract

We discuss the prospects for Chinese money market development and transition to market-based monetary policy operations based on a comparative historical analysis of the present Chinese situation and the development in 11 European countries from 1979 up to the launch of EMU. Central banks in the latter typically had an incentive to encourage the formation of efficient benchmark segments in the domestic money markets for the conduct of open market operations as traditional quantity-oriented instruments became increasingly ineffective. China is displaying many of the same symptoms as the European countries in the 1980s including poor monetary transmission due to excess liquidity, and conflicts of interest due to unclear priority among multiple policy goals. We conclude that the current Chinese multiple-target monetary policy is counter-productive to efforts to develop an efficient money market which can serve as arena for an effective market-based monetary policy.

1. Introduction

The reforms of the operational aspects of monetary policy in the last 20-year period on the one hand, and financial deregulation and innovation on the other, are here argued to be part and parcel of the same process. The operational framework of monetary policy is intimately related to the institutional environment in which it is conducted, and the evolution of the practical aspects of policy-making interplays in a complex way with the general path of financial market development. For example, the structure of the money market determines the extent and type of open-market operations that are feasible; conversely, evidence and experience indicate that favorization by the monetary authorities of market-oriented policy instruments helps to foment a broader market development.¹

This paper focuses on the relationship between money-market development and monetary policy choices, with the motivation that the implementation, as well as the underlying ‘philosophy’, of monetary policy have undergone radical changes in most industrial countries during the last few decades. These changes have been paralleled by a similar radical development of financial markets – including money markets, which are the main ‘forum’ for the implementation of monetary policy. China is currently undergoing a similar development (although from a somewhat different starting point). The parallel processes of financial market development and reorientation of monetary policy are intertwined, and have domestic (political) roots, as well as being greatly influenced by increased cross-border capital mobility. The idea of the development process as a continuous interplay of market outcomes and policy choices is a fundamental underlying hypothesis of the whole study.

The monetary authorities—usually the central bank—may rely on a host of instruments to achieve its objectives, whatever these objectives may be.² These instruments usually fall into one of three categories: direct regulations (for example, interest-rate regulations and

credit ceilings), standing facilities (deposits and loans at the central bank available to banks at their own initiative), or discretionary operations (for example repurchase transactions, foreign-exchange swaps, issuance of central-bank securities or outright transactions in short-term markets). In the post-WWII period up to the mid-1980s, most European central banks used to rely primarily on the two former categories. The general conditions for monetary-policy making were such that regulations were favored and the scope for discretionary operations in the absence of developed money markets was severely limited. The regulations in force also typically served multiple purposes. As a consequence, it was often difficult to separate monetary policy from other types of policy.

Deregulation of financial markets largely coincided with, or was conditional of, a general reorientation of monetary-policy operating procedures. Both the tools used by central banks and the variables on which the tools were designed to operate largely shifted, essentially from a Keynesian growth- and full-employment-oriented monetary policy operating on monetary aggregates, to an inflation-oriented monetary policy operating on interest rates, and playing on market terms.

In this paper, we try to extract lessons from the European experience for China. China is committed, under the World Trade Organization (WTO) agreement, to opening its financial sector by the end of 2006. Opening up the financial system implies removal of a large number of administrative restrictions, controls and regulations currently in use. Required reforms include opening up the capital account, liberalizing interest rates, and allowing foreign banks full access to the domestic market. Because money markets are a key link between a country's financial system and its real economy, and the primary arena for the conduct of monetary policy, the lack of properly functioning money markets is presently a key missing piece of the puzzle in China, as the development toward a market economy in other sectors and commitments under the WTO agreement have taken the need for reforms of beyond the point

of no return. The traditional 'dirigiste', direct-control approach to monetary policy is ineffective as it is; with a more open financial system, an indirect market-oriented approach will have to be put into place. Lessons from the bond market deregulation are to clean up the back yard before bringing in the guests (see Oxelheim, 1996). In terms of financial deregulation, this means to sort out the domestic financial system before the capital account is fully opened. In terms of monetary policy, it emphasizes the link between financial deregulation and reform of operating procedures.

The 11 European countries in our study are all examples of small, open economies. Although potentially an economic giant, the size of the Chinese economy and its dependence on external markets during the 1990s and early 2000s make it more comparable with small and open, rather than with larger, economies. The European focus countries are: Austria, Belgium, Denmark, Finland, Greece, Ireland, the Netherlands Norway, Portugal, Sweden and Switzerland. Apart from the fact that they are small and open, the choice of case countries is motivated by the fact that the money market for these countries' currencies were virtually non-existent at the beginning of our study period (1979–2000), but have since gone through phases of emergence, growth, sophistication and international integration. The countries also represent the full spectrum with regard to the level of ambition of exchange-rate policy, and 'reputation' in monetary matters: from hard-currency, low-interest-rate countries like Switzerland, the Netherlands and Austria, to countries which during part of the period investigated here had a near-emerging-market status (Greece and Portugal). We argue that due to this diversity, the 11 countries constitute an excellent 'laboratory' with regard to the link between money market development and the conduct of monetary policy.

The choice of study period is based on *ex ante* knowledge about the approximate historical point of departure of the financial-market 'transformation' process. The current

state of money market development in China shows similar traits with the European countries' point of departure.

The paper is structured in the following way. In section 2, main developments in domestic money markets are reviewed. These are largely comprised of two interlinked processes: that of deregulation and liberalization on the part of authorities, and that of innovation and growth on the part of 'markets'. These two processes are treated in separate sub-sections. Section 3 mirrors that of section 2 in that it analyzes the changing operative procedures of central banks along two lines: the decreasing role of direct controls (closely related to the general deregulation of financial markets), and the increasing role of discretionary (open-market) operations. Comparisons within the group of European countries and between China and these countries are made throughout. In section 4, we identify the main drivers of changes in central-bank operations, and analyze the extent to which they are applicable to China today. Thereafter, we assess the effectiveness of central bank operations. Section offers conclusions.

2. General developments in domestic money markets

The European countries covered in this paper all followed the general trend among industrial countries of broad-based financial-sector deregulation in the 1980s and 1990s. Below, we make a brief summary of that process.³ We then go on to describing major trends in financial innovation, differentiation, and market growth, with a focus on short-term securities markets (money markets). The findings are used for comparisons with the present state of affairs in China.

2.1. The point of departure - Stylized fact of the European situation 1980 and China today

The regulations in force in a majority of European countries until the 1970s or, in most cases, the 1980s were of the following major *types*: pricing regulations (mostly various types of interest-rate regulations), a wide variety of quantitative credit and investment regulations, issuing controls on financial instruments, market-entry rules and ownership (asset) restrictions. The different types of regulation one by one are described below.

Interest-rate regulations were in force in all countries in the sample except the Netherlands at the start of the period covered here. Several countries pursued a low-interest-rate policy which, in combination with high inflation rates, led to very low (or even negative) real-interest-rate levels. This, in turn, led to a high credit demand, indicating that credit had to be rationed and the market as a whole had to be regulated in detail, both as regards prices and quantities.

Quantitative credit and investment restrictions, in one form or another, were employed in a majority of the countries here included, both as a general monetary-policy instrument, as a tool to ration and control the allocation of credit, and to provide cheap financing for the government.

Issuing restrictions on securities were used to control the transfer of credit through direct channels (that is, through market issues). Usually, rules and regulations on minimum maturities, etc., were combined with various authorization requirements.

Market-entry rules or line-of-business regulations—the separation of banking and securities businesses, the separation of commercial banking from investment or savings banking, and other branching restrictions—limited the segmental integration within the financial system. A similar effect is implied by regulations limiting *ownership* linkages between different types of financial institutions, between financial institutions and other industry sectors, between domestic and foreign institutions, etc. In addition, a sort of ‘ownership restriction’ was the dominance in some countries of state-owned banks at this

period. This applies primarily to the countries with previously entirely nationalized financial sectors (Greece and Portugal), but also, to some extent and during some periods, in other countries. In Norway, for instance, indirect control by the government of the financial sector through ownership of major banks was one consequence of the banking crisis around 1990.

As can be seen from Table 1, which summarizes the situation around 1980 in terms of regulation in the sample countries, several countries applied all major types of regulations. Portugal, for instance, was in 1980 very much still marked by the effects of the nationalization of the financial sector in 1974 and a system whereby the Banco de Portugal was equipped with almost limitless authority to intervene in all aspects of financial intermediation. All or most regulation types were also used, for instance, in Austria, Greece, Norway and Sweden.

As can also be seen from the table, the same holds true for China in the mid-2000s. In spite of steps toward deregulation, the financial system is still repressed and based on regulatory infractions in financial market activity.

[Table 1 about here]

2.2. Deregulation and liberalization of financial sectors

In this section we describe what happened in our case countries in terms of deregulation and liberalization.

Interest-rate controls began to be dismantled in the late 1970s in Austria, Denmark, Ireland, Norway and Sweden. By the mid-1980s, Denmark, Norway and Sweden (beside the Netherlands) had completely deregulated interest rates. Nor had Ireland by this time any formal interest-rate controls, but (retail) interest rates were loosely controlled through informal agreements between banks and the central bank until the mid-1990s. Interest-rate liberalization in these countries was completed with a lag to the very earliest deregulators

(apart from the Netherlands primarily Germany, Canada, Australia and New Zealand), but with a lead to most of continental Europe, where the main steps were taken in the second half of the 1980s.

By 1990, also Austria,⁴ Finland and Switzerland had completely liberalized interest rates; Belgium had, in principle, also deregulated interest rates, but retained some minor controls on specific categories or types of credit. The last among the survey countries to abolish interest-rate regulations, Greece and Portugal, completed the process a few years into the 1990s, in accordance with their gradual implementation of European-Community directives. (See Rautava, 1994; Edey and Hviding, 1995.)

The general pattern seems to have been that the liberalization of wholesale interest rates occurred first, followed by lending rates and deposit rates.⁵ The process was mostly gradual, and sometimes hesitant on the part of the authorities. An illustration of this is that formal rules and restrictions (a ceiling, a quota, etc.) were often initially followed by recommendations or various types of agreements before being de facto liberalized. This was the case in Belgium, Denmark, Greece, Norway, Portugal, Sweden, as well as other countries (Austria and Ireland were mentioned previously). These ‘implicit’ interest rate regulations were enforced through the understanding that the authorities could, and would, enforce their goals by means of the reinstatement of formal regulations if deemed necessary (see, e.g., Grønvik, 1994).

In China, interbank interest rate ceilings were abolished in 1996, the central bank rediscount rate liberalized 2004, and the lending interest rate ceilings for banks were removed in 2004. The interest rate liberalization process is still ongoing, however, and administrative influence over price-setting is probably still substantial – if not directly then indirectly and implicitly (Green, 2005).

As noted above, there is a clear co-dependence of various types of regulations. Thus, *quantitative regulations* to some extent became obsolete or irrelevant as interest rates were

being liberalized.⁶ By that token, the quantitative regulation of financial intermediation was overhauled in Austria, Denmark, Finland, Ireland, the Netherlands, and Sweden in the first half of the 1980s. Belgium had begun doing so in 1979, but the process took more or less the entire 1980s to be completed. Of the other countries, Switzerland had not applied quantitative controls since the 1970s. Norway abolished credit regulations in 1988, Portugal around 1990, and Greece a few years into the 1990s. Credit quotas were formally abolished in China in 1998, but the People's Bank of China (PBC), the Chinese central bank, still routinely controls the quantity of credit on a more discretionary basis (see, e.g., BIS, 2005, and references given below).

The regulation of debt securities issuance was mostly in place for slightly longer than interest-rate and credit controls. Exceptions are Denmark (which had a relatively free and internationally oriented bond market based on private debt already in the 1970s), and the Netherlands, where regulation was comparatively limited. Switzerland was low on formal regulation, but the growth of the domestic market segments was hampered by business practice, as well as by tax policy and other factors. Finland, Ireland, Sweden and Switzerland lifted issuing controls in the first half of the 1980s. In some countries important liberalization measures were implemented in the mid-1980s (for instance in Norway – see *Norges Bank, Penger & Kreditt*, 26:1, 1997). The Netherlands, although comparatively liberal in several respects, applied rules on minimum maturities, which constrained the development of short-term markets, and were fully abolished only in 1990.

In other countries, important steps toward the opening-up of securities markets occurred in the context of a reform of government-financing systems. Such is the case, for example, in Austria and Belgium (around 1990; see De Broeck *et al*, 1998), and Greece (early/mid-1990s, see Soumelis, 1995). Generally, however, the liberalization of markets for private debt was slower than other categories. For instance, the Portuguese fixed-income market was not

formally opened to all domestic issuers until 1994 and to foreign issuers 1995 (see de Pinho, 2000). Also, as previously mentioned, market development was in some cases stifled by the existence of various types of more or less informal authorization requirements. For instance, Switzerland abolished numerous cartel-like conventions and permanent securities-issuance syndicates of banks in 1990.

In China, securities issuance (both debt and equity) remains surrounded by formal and informal restrictions. The government's characterization of the existing stock exchanges as 'controlled experiments' is illustrative of the general attitude of the authorities.

Various *market-entry regulations* (branching regulations, line-of-business restrictions, etc.) were partly or wholly abolished in the 1980s and early 1990s in some of the case countries, including Austria, Belgium, Denmark (where de-compartmentalization of the banking sector occurred already in 1975), Finland, Norway and Sweden. Moreover, a 'spontaneous' functional market integration (taking place, for instance, through banks establishing subsidiaries within the securities-trading business, or purchasing finance companies) is often considered a major feature of the financial-market transformation process undergone by the industrial countries in the 1980s.⁷ To some extent, this implies a diminishing practical importance of remaining regulations.

To this category may also be counted restrictions on foreign-bank entry. In the sample, Finland, Norway, Portugal and Sweden were among those countries that opened their domestic markets for foreign banks during the 1980s. In some other countries, including the Netherlands and Switzerland, rules on foreign-bank access to the domestic market were already relatively liberal at the start of the 1980s, whereas in much of the rest of the continental-European countries, significant steps were taken only with the implementation of the EU's 2nd Banking Directive (effective in 1993).

In the area of ownership control, the deregulation wave made a comparatively modest impression in the 1980s and 1990s, and several such regulations remained in the mid-1990s (see, e.g. Herring and Litan, 1995). State-ownership of a large proportion of domestic financial institutions also outlived financial integration in some countries. The Greek banking sector, for instance, was still completely dominated by state-owned banks when ownership regulations were abolished. In terms of assets, the government's ownership share was about 75 percent (see Hope, 1993). In other countries, state-ownership of banks was an effect of crises in the banking systems, as noted above. The government's ownership share of banks in Norway and Finland were 52 and 35 percent, respectively, in the early 1990s.⁸

State-owned banks dominate the financial sector also in China. The four state-owned banks had a market-share of 57% in 2003. Local banks 20%, 10 joint stock commercial banks 14%, three policy banks 8% and foreign banks 1% constitute the rest of the Chinese banking sector (van der Linden, 2005). Institutional reforms of PBC and state-owned banks have been undertaken since 1993, however, still largely unsuccessful, because they do not fundamentally alter incentive structures within the banking sector (see, e.g., Park and Sehart, 2001). A five-year time-table for a gradual opening of the banking sector was announced in 2001. A full abolition of line-of-business, ownership and foreign-entry restrictions in the banking sector is projected to end-2006 (as a result of WTO negotiations).

To summarize, the deregulation of domestic financial sectors in the European case countries began between the late 1970s (Austria, Scandinavian countries) and the mid-1980s (Greece, Ireland), and was completed mostly around 1990, or a few years into the 1990s. In China, liberalizations began in the mid-1990s. It is difficult to measure the level of repression, but based on the categories of restrictions still in *de facto* use in the mid-2000s, it would appear as though the process still has some way to go.

2.3. Money market growth and development

Some ambiguity exists as regards the definition of the money market and its segments. The money market is usually defined as a market for short-term debt (generally with original maturities of up to a year). One main segment of money markets is the interbank market. The other segments are the primary and secondary markets for various short-term securities, and the derivatives market. The foreign-exchange (FX) markets and domestic money markets are also closely interlinked through the existence of markets for forward-exchange contracts and swaps, which make certain types of FX transactions equivalent to single-currency transactions. Because the interbank segment is defined *in terms of participants* and the ‘open-market’ segments usually *in terms of instrument* there is a considerable overlap between these segments. The interbank market is sometimes taken to mean the market for very short-term, that is, overnight up to a few weeks, deposits and loans. Central-bank facilities for such deposits and loans are included. Virtually all types of instruments - including derivatives - are traded interbank. The segmental structure is therefore not wholly clear, and tends to vary somewhat from country to country.

[Table 2 about here]

Table 2 summarizes starting years for some of the main money market segments in the European case countries and in China. In the former, during the 1980s and 1990s a certain convergence in terms of the *presence* of different types of money-market instruments occurred. Considerable dissimilarities remained, however, in terms of the relative total size of the domestic market as well as in terms of the *relative importance* of specific segments of the market (see Table 3).

[Table 3 about here]

The most traditional money-market segment is the interbank deposit market, whose importance is largely determined by the monetary authorities' choice of operative framework and by the existence of alternative segments. Deposit markets turned up in most countries as monetary-policy instruments changed during the 1980s and 1990s. In China, the CHIBOR interbank market was established in 1996.

In the short-term securities markets treasury bills or equivalent short-term government securities are typically the most important sub-market. In several countries (for example, Austria, Belgium, Ireland, Sweden), short-term government securities had existed for a long time before the 1980s, but were traditionally non-marketable, and sold directly to final holders at regulated rates. In none of the European countries here considered did true markets for t-bills turn up until after 1980. Years in Table 2 therefore refer to the appearance of *viable markets* for short-term government securities. The Chinese t-bill market is so far insignificant. Outstanding bonds (government only) are at about 20% of GDP (2004). The maturity structure of bonds is such that less than 5% are 2-year or less, indicating a short-term (government) bill market of somewhere around 1% of GDP.

Two other main cash-instrument types—commercial paper (generally issued by non-bank entities) and certificates of deposit (a securitized bank liability)—were introduced in several countries in the mid-1980s, but as revealed by Table 3 their importance varies greatly. In some cases (for example Finland and Sweden), the introduction of CDs preceded the introduction of tradable government securities. In other cases, diversification of the market to other than government issues occurred several years after a t-bill market—in a true market sense—had been established (Ireland, the Netherlands, Portugal). A CD market does not exist in China beyond the PBC's own central bank bills, which were introduced in 2003. The

development of this segment has been fast, however, with an increase of outstanding amounts to an estimated 7% of GDP in March 2005.

Commercial-paper markets have emerged in far from all the countries here covered. In many cases, the markets have also shrunk somewhat from their peaks in the early 1990s. There seems to be some indications that where commercial-paper markets could be benchmarked against a liquid government-bill market (or other instrument with a market-supporting role), their development came earlier and was more extensive (see Alworth and Borio, 1993). In China, the PBC announced rules for issuance of ‘short-term financing bills’ in late 2004 but no viable market exists by mid-2005.

Beyond the above reported cash instruments, various derivative instruments play an important role, as do repurchase agreements (repos), which – according to BIS estimates – was the fastest growing instrument/transaction type internationally during the 1990s. Data, however, are scarce. Reporting in different countries is also such that available historical data are not readily comparable (for a survey of repo markets in G-10 countries, including data availability, see Bank for International Settlements, 1999). Existing data indicate considerable variations in derivatives as well as repo markets (see Forssbäck & Oxelheim, 2003). In some countries, repo markets were partly stifled due to thin debt markets (the Netherlands, Norway), ambiguities with regard to regulatory policies, legal status and tax treatment (Ireland, Portugal, Switzerland), or an excessively high degree of concentration of market players (see Commission of the European Communities, 1999). A repo market was established in China in the early 1990s; since 1997, it is split up into an interbank market and a corporate market (hosted by the Shanghai Stock Exchange). Data to assess the size and importance of the market are lacking, but given the limited supply of financial assets to underpin repo transactions, it is not likely to be particularly important (also see section 3.2,

below). A first set of rules to govern Chinese banks' derivatives trading was introduced in 2004, but a viable market does not yet exist (de Teran, 2004).

3. Changes in central-bank operations⁹

Until the mid-1980s central banks in industrial countries relied largely on traditional credit and deposit facilities (standing facilities), supported by various direct controls, for the conduct of monetary policy. The ordinary credit facilities were mostly supplemented by some sort of tranche-division system (for example, Denmark, Finland), penalty-rate system (Austria, Sweden), or a combination of both (Belgium, the Netherlands) in order to allow central-bank control of the marginal cost of banks' borrowing under the facilities, and thereby of the supply of liquidity to the banking system.

All our European focus countries reformed their operative frameworks for monetary policy quite substantially during the 20 years we study. In some countries, the revision of the monetary-policy operating framework took the form of comprehensive reforms (for example, Denmark 1992, Switzerland 2000); in others, developments proceeded in a more piecemeal manner. In several countries (Belgium, Finland, the Netherlands) the trend toward a gradually increased diversification of liquidity-supply instruments became visible toward the mid-to-late 1980s. Others followed suit during the 1990s (Denmark, Portugal, Austria).

3.1. The diminishing role of quantitative controls

The diversification of instruments used by central banks as well as by other money-market agents in our focus countries during the 1980s and 1990s was paralleled with the lifting of most direct regulations. This sub-section therefore focuses on one direct control that remained in use by many central banks—the minimum reserve requirement.

During the 1990s, practically all our European case countries followed an international trend among industrial countries toward lowering or completely abolishing reserve requirements (see Table 4). The major arguments behind these reforms were to reduce the tax effect of reserve requirements and to neutralize the competitive disadvantage of subjected depository institutions vis-à-vis other financial institutions – domestic or foreign (see European Commission, ‘Minimum Reserve Requirements and Monetary Policy’, *Weekly Review of Financial Market Developments* 37, November, 1997).

The objectives of the reserve-requirement instrument were originally to maintain banks’ liquidity even in case of large deposit withdrawals, and to influence liquidity for monetary-policy purposes. Nowadays, reserve requirements serve three main purposes in developed economies. One is as a means of providing for banks’ ongoing liquidity needs (having banks in a position of reliance on the central bank facilitates the conduct of monetary policy). A second purpose is to improve the flexibility of banks’ liquidity management (reserves can be used to settle interbank payments). Finally, reserve requirements (particularly if unremunerated) can provide seigniorage income for the central bank, thereby contributing to its profitability and (economic) independence (see, e.g. Grønvik, 1994; Bank of Finland Bulletin 12, 1996; BIS, 2003).

[Table 4 about here]

[Figure 1 about here]

Countries that abandoned the use of reserve requirements more or less entirely relatively early on include Belgium (mid-1970s), Norway (1987) and Sweden (1990). In Norway, for example, both primary reserves (that is, cash-reserve requirements) and secondary reserves

(compulsory bond holdings by banks and insurance companies) had been used since the 1960s. From 1971 only the primary reserve requirements were used in Norway, but they were altered often and by much.

Minimum reserve requirements did play a role (at least formally) as liquidity-management instrument until the late 1990s in the Netherlands and, to some extent, in Austria, Finland, and Ireland. However, the only country where they played a significant role for active liquidity management in the late 1990s was Greece (until its entry into the EMU), where the instrument was deemed necessary to retain control over the liquidity supply in the face of large capital inflows. This parallels earlier experiences in, for instance, Portugal, other emerging market economies, and the present situation in China, where since the 1990s the PBC still relies heavily on reserve requirements to manage liquidity. China has lowered reserve requirement ratios since the 1980s and 1990s (see Figure 1), but there is no clear-cut trend, and an indication of the PBC's continued reliance on this instrument type is its introduction of a differentiated reserve requirement system in 2004 to increase flexibility and precision. However, minimum reserve requirements do not bite as a monetary policy tool unless a properly functioning pricing mechanism in the money market gives banks an incentive *not* to put their liquidity into reserves (i.e. keep them close to the minimum requirement). This is not the case in China, where 1998-2004 the reserve holdings of the banks have more or less consistently been in excess of 5 percent beyond the required ratio (Green, 2005).

3.2. The increasing role of market instruments in central-bank operations

Three main types of market instruments predominate: short-term securities, repurchase operations, and swaps. The prevalence in our focus countries of these main instrument types is examined in the present subsection.

Effective open-market operations to some extent presuppose an existing market to operate in. Thus, central banks have typically, at some point or another, come to favor the creation of markets, and have often stimulated and supported their development. This holds for interbank deposit markets as well as for short-term securities markets.

The absence of an efficient interbank market is bad news for the central bank to the extent that banks then may rely on central-bank facilities to gain access to liquidity even when other banks are very liquid, creating a situation of excess liquidity in the banking system and poorer monetary transmission.¹⁰ For monetary policy to bite, banks' *marginal* liquidity needs must be settled with the central bank. Hence there is a need for central banks to create adequate instruments to drain liquidity and to stimulate the formation of markets for alternative short-term assets. Instead, traditionally, specific credit quotas to individual banks were used to atone for this problem. In the general climate of decontrol in the mid-1980s, however, it seems ultimately to have been widely accepted that stimulating the emergence of efficient markets was a more constructive path to pursue. Examples are the establishment of efficient day-to-day interbank markets in Belgium and Sweden (in both cases around 1985–88), which were more or less anticipated effects of changes in the layout of monetary-policy operating procedures (BNB, 1985; Kneeshaw and Van den Bergh, 1989). More generally, the emergence of a markka money market was stimulated by the Bank of Finland's decision to leave the forward exchange market to the devices of the banks themselves (around 1980). Parallels exist in, for example, Denmark and Portugal (see Danmarks Nationalbank *Monetary Review*, August 1996; and Pinto, 1996).

The emergence of short-term securities markets adds a dimension to liquidity management for central banks. In practice, cash operations in short-term securities by central banks are relatively rare, even where the size of these markets is sufficiently large to make such operations feasible (see Borio, 1997; BIS, 2003). One reason is that other types of

operations are more flexible. Other reasons which have carried some weight in several countries are the wish to avoid potential conflict with other public-policy objectives (notably public-debt management, for example in Denmark and Portugal, and tax policy), and the wish to avoid circumvention of limits on central-bank lending to the government.¹¹

To avoid conflicts of interest and to increase the effectiveness of monetary policy, it has been relatively common for central banks in small countries to issue their own securities (central-bank CDs) in the primary market in order to absorb liquidity from the banking system. In some cases, this has been one of the main strategies of the central bank. Countries where the issue of central-bank paper has played an important role during shorter or longer periods include Finland, Ireland, the Netherlands and Portugal among the EMU countries, and Denmark and Sweden among non-EMU countries. This is currently the main type of market operation in China (see section 2.3).

Even in the absence of outright transactions in securities, the existence of a liquid securities segment in the money market is often argued to facilitate the central bank's operations by providing collateral to repurchase agreements and similar collateralized transactions. To the extent that it does so, the varying degrees to which short-term securities markets have emerged in the review countries imply correspondingly varying possibilities for the respective central banks to exploit the flexibility and other advantages of repurchase agreements and similar instruments.¹² During the course of the 1990s, repurchase transactions were adopted as a main liquidity-management instrument in Denmark (as from 1992), Sweden (1994) and Switzerland (1998), in Austria (1995), Finland (mid-1990s), the Netherlands (refers to 'special loans') and then, from the time of its inception in 1999, in the whole Eurosystem (see Table 5).

[Table 5 about here]

In principle, of course, any type of security—not just short-term securities—may be used to underpin collateralized transactions. The common argument that efficient short-term securities markets are needed for the conduct of open-market operations by central banks is therefore not necessarily particularly strong.¹³ Recent developments, in which the ECB has gradually expanded its palette of security types eligible for collateral in repurchase operations, is also an illustration of this. In the US (BIS, 2001) and the UK (Bank of England, 2002), where that palette is somewhat narrower, the debate in the early 2000s has been more concerned with the ‘quality’ (rather than the original maturity) of the collateral: more specifically, the concern has been with the feasibility of open market operations and the eligibility of private securities for central bank operations in an environment of declining government issues (see, e.g., McCauley, 2001, and Wojnilower, 2000).

In China, the PBC started cash trading of government bonds in 1998. Repo transactions in bonds started in the late 1990s; temporary reverse repos in bonds in 2002 but operations then seized because of inadequate supply of bonds. The question here too, then, is not so much the original maturities of the assets, but the absence of a market at all. Government issues are all that exists in the medium-to-long-term segments; the short end is dominated by PBC bills, but there is scant demand for either, because the pricing mechanism does not work.¹⁴ The general conclusion in terms of the PBC’s open market operations is that debt markets in the mid-2000s are too shallow for effective buy-sellback or sell-buyback operations.

Some countries without liquid short-term markets have relied on foreign-exchange operations (particularly swaps) for liquidity management. The pre-eminence of swaps over spot or regular forward-exchange operations simply reflects the greater importance of swaps in the interbank market. Swaps are the major instrument by which banks cover their forward

foreign-exchange commitments to customers (See Hooyman, 1994). Countries where FX swaps have played a significant role for liquidity management by the central bank and/or by the banking system as a whole include Austria, the Netherlands and Denmark. In Switzerland, USD-CHF swaps were the principal market operation of the National Bank during the period between the early 1980s and the late 1990s.¹⁵ A Chinese foreign exchange swap market was established in 1980 after the first restrictions on foreign exchange transactions were removed in 1979, and an interbank foreign exchange market introduced in 1994 as the dual exchange rate system was abolished (Yang et al., 2004). In the mid-2000s, these markets do not play any role for the central bank's liquidity management with the domestic banking sector (BIS, 2003).

4. Changes in central-bank operating procedures: main drivers

Because financial market regulations were partly designed as monetary policy instruments, the deregulation process is in itself sufficient reason for reformation of the operational framework of central banks: as some policy instruments are taken away, others must replace them. Beyond this, the literature and the central banks' own accounts offer five main reasons for the more or less universal reform of central bank operating procedures in industrial countries in the 1980s and 1990s (see, e.g., Mehran et al., 1996, and Forssbäck and Oxelheim, 2003, for elaborations).

First, monetary-policy instruments were changed in several countries in order to adapt the operational frameworks of the respective monetary authorities to new regimes and/or new targets for monetary (and exchange-rate) policy.

Second, the financial deepening of the economies occurred more or less entirely outside the central banks' balance sheets, and therefore reduced the share of the financial system over which monetary authorities could exert direct control. The result was an increasing need for

indirect ways to exercise control over the non-monetary components of the money supply (price-oriented as opposed to quantity-oriented instruments).

A *third* factor relates both to the expansion and diversification of financial markets domestically and to the increasing international integration of financial markets. Greater interest-rate flexibility and narrowing differentials between rates of return in different currencies gave rise to the need for instruments whereby liquidity (and thereby interest rates) could be managed more *flexibly* in time and in magnitude, and with a greater measure of *accuracy* than that offered by, say, discounting, interest-rate controls, and lending ceilings.¹⁶

Fourthly, the increasing importance of *expectations* in a world of free financial markets favored the adoption of instruments better suited for *signaling* the central bank's monetary policy stance.

A *fifth* broad category of reasons relates to the wish more generally (on the part of monetary authorities) to stimulate money-market activity and improve monetary-policy transmission, and to achieve a clearer separation of monetary policy implementation from government-debt management, and from other social-policy goals (favoring certain sectors in the economy by granting access to cheap credit, etc.) which were auxiliary reasons for the imposition of financial-market regulations. Because financial regulations were often of a multiple-purpose variety, and because the central bank was typically responsible for the implementation of the regulation policy, the distinction between monetary policy and other 'types' of policy had previously not always been very clear-cut.

Do these five reasons apply to the Chinese situation today? The simple answer is no, not generally. The objectives of monetary policy remain manifold and not necessarily compatible, and the priorities between different goals are unclear – in other words, no major regime shift has taken place; the financial system – as we have seen – is still underdeveloped, and financial intermediation beyond the explicit or implicit control of the central bank is limited;

as a result of the former, and due to the remaining financial repression, the role of expectations is still limited. Reasons three and five, however, deserve closer attention in the Chinese case. There *is* a need for more flexible and accurate instruments, and it *is* a declared objective of the PBC to stimulate money market activity and improve monetary policy transmission. The reason is – simply, and in parallel with several of the European countries – that monetary policy presently is ineffective. The reason it does not work, however, is not obviously the same. In the next session, we make an attempt to analyze the main reasons behind the ineffectiveness of Chinese monetary policy, building on the European experience.

5. Effectiveness of monetary policy: the PBC's recent performance in light of European experiences in the 1980s and 1990s

A very brief summary of the PBC's recent policies and performance runs as follows. After the abolition of the dual exchange rate system in the mid-1990s, a fixed exchange rate regime was adopted whereby the RMB was pegged to the USD. Current account convertibility was adopted in 1996, after which restrictions on capital inflows were gradually removed. Monetary policy was partially designed to support a more general policy to attract foreign direct investment (FDI) inflows. In 1998–2001, the PBC made (largely unsuccessful) attempts to increase credit growth through open market operations and lowering of minimum reserve requirements. From 2003 onward, the attempts have rather been to tighten monetary policy, however with equally limited effects of the 'standard' arsenal of instruments. The PBC has frequently had to resort to moral suasion, various forms of *ad hoc* administrative measures and 'open mouth operations' to steer banks' behavior in the desired direction (BIS, 2005; Green, 2005; Roach, 2004; van der Linden, 2005).

Steps have been taken to deregulate capital outflows and expand permissible foreign exchange transactions since the early 2000s. As a step toward gradually increasing the

flexibility of the exchange rate (after intensive international debate – see, e.g., Eichengreen, 2004; Goldstein, 2004; Prasad et al., 2005; Yang et al., 2004), the US dollar peg was abandoned in July, 2005, the RMB revalued by 2.1% and henceforth linked to a currency basket through a managed float system.

The poor transmission of monetary policy is due to deficiencies both in the step between the central bank and the banking system, and between the banks and the public. Five such deficiencies can be identified: 1) The non-responsiveness of the banking system to the central bank's policy (in particular, their insensitiveness to interest-rate changes) is largely due to the excess supply of liquidity. If banks do not have to borrow in the money market to meet their liquidity needs, they do not care about the price at which money can be borrowed there. 2) As a consequence of banks' own insensitiveness to pricing of money, they do not appropriately pass on variations in these prices to their customers; hence, central bank policy has a very limited effect on the consumption and investment behavior of firms and households. 3) Even if interest rate changes are passed on by banks on the margin, the effect is diluted, since the banks have limited ability and incentive to adequately price risk and differentiate the price of credit to different categories of borrowers accordingly (cf. governance problems within the banking sector below). 4) Borrowers are themselves insensitive to variations in the cost of funds because they do not face any consequences in the event of failure to service the debts (state-owned enterprises), and because credit-driven consumption is still extremely limited (households), and finally, 5) The continuing habit of the PBC to exert control over the quantity of credit (and the sectors to which it is given) as a means to achieve policy objectives distorts the market mechanism in the bank loans market, leading to continuing mis-pricing and mis-allocation of credit.

Forssbäck and Oxelheim (2003) empirically analyzed the sources and effects of fluctuations in money market liquidity in a sample of European countries over the 1980s and

1990s. Four tentative conclusions emerged from their results related to the effectiveness of monetary policy operations. Since they are useful for the analysis of the Chinese development they are summarized below.

First, autonomous factors are often the most important sources of liquidity fluctuations in the domestic money market. The central bank is frequently ‘unsuccessful’ in offsetting these influences other than imperfectly. In short, this means that the job of the central bank is primarily to forecast and offset factors outside its direct control that influence the domestic market, and only then (marginally) to ‘steer’ the money market.¹⁷ The two most important autonomous sources of fluctuation in money-market liquidity (and thus the major factors that the central banks have to counter in their policies) are net foreign assets and net lending to the government. The net-foreign-assets portion of the autonomous position should—all else equal—be more variable in countries with far-reaching exchange-rate commitments, where the central bank has been active in the foreign-exchange market or in other ways made more extensive use of foreign-exchange reserves to uphold that commitment. However, Forssbäck and Oxelheim instead find that net foreign assets are a more important source of liquidity fluctuation in ‘weak-currency’ countries (regardless of exchange-rate regime), and a less important one in ‘hard-currency’ countries.

This leads up to the *second* main conclusion: non-credible policy (for example exchange rate) commitments lead to ineffective central bank operations. If the central bank’s target variables are influenced to a great extent by factors beyond its control, then not only is the effectiveness in achieving the desired policy goals impeded, but so also is its choice among the range of instruments at its disposal, as well as its capacity to influence the overall structure of the money market.

Thus, *thirdly*, autonomous factors affect central bank instruments and money market structure. On a more general level, this emphasizes the need for *consistency* in the policy pursued.

The consistency issue links the third conclusion to the *fourth* one. Economic independence of central banks leads to more effective central bank operations and vice versa. If economic independence of the central bank can be approximated by the influence on liquidity fluctuations over the central bank's balance sheet of net lending to the government, then the central bank's ability to effectively anchor money market interest rates and to stabilize the exchange rate, is increasingly impeded the more it has to counter liquidity fluctuations resulting from the obligation to fulfill other public-policy goals (such as government financing).

Below, we use these four conclusions in order to structure a discussion about the roots of the present ineffectiveness of Chinese monetary policy.

Based on conclusion 1 above: Large capital inflows and resulting build-up of foreign exchange reserves has been the most important source of liquidity in the early 2000s. Base money growth has trend wise increased from 2% to 17% between 1998 and 2003 (Goldstein, 2004). Foreign exchange reserves as percent of GDP has increased from 15% the first quarter 2001 to 40% at the end of 2004 (Goldstein, 2004). The PBC's operations during the last few years have largely been geared toward offsetting these undesired money-supply effects of capital inflows.

Estimations by Green (2005) show that the PBC's open market operations are almost perfectly correlated with capital inflows. Yet, Green reports that the operations are able to sterilize less than 50% of the effect of these inflows on the money supply. According to the estimates, between the middle of 2004 and early 2005, foreign exchange inflows added cumulatively to the money base in the order of RMB 100 bn per *month*, indicating an annual

growth rate of around 70%. The asymmetry of capital controls giving a bias toward net capital inflows has exacerbated this problem.

Based on conclusions 2 and 4 above: The multiple, and often incompatible, goals of monetary policy – fixed dollar exchange rate, inflation, growth, employment, financial stability, etc. – are evidently a major problem for Chinese monetary policy. The very recent problems of the PBC to make monetary policy ‘bite’ are clearly influenced by the exchange rate regime, for example. Given the level of financial risk in the economy, the possibility of misleading interest rate levels, and other factors, it is not obvious that the currency is/was under-valued (for discussions, see, e.g., Eichengreen, 2004; Goldstein, 2004; Prasad et al., 2005); whether it was or not, however, it would appear as though a revaluation came to be expected for at least two years before the modest revaluation was finally implemented in July 2005. This partially explains the troubles of the PBC of conducting a monetary policy which was much too expansionary for domestic conditions, but still not expansionary enough to keep capital inflows at bay (the share of non-foreign direct investment inflows also significantly increased during this period; see BIS, 2003, 2005; van der Linden, 2005). In short, the exchange rate goal was non-credible, which worsened the conditions for monetary policy operations. More generally, an exchange rate stability goal increasingly undermines monetary policy autonomy as capital controls erode, which – by definition – compromises some or several of the other goals.

Not just non-credible exchange rate goals disturb monetary policy; another example may be the attempts to simultaneously achieve the goals to safeguard financial stability and prop up employment in the publically owned manufacturing sector. Large state-owned enterprises are squeezed by remaining commitment to production planning, and are unable to compete with the private sector. State-owned banks are forced to finance state-owned enterprises (SOE) with successively new loans (which are frequently not repaid), in order to

avoid large-scale unemployment and social unrest. Remaining political influence over the banking sector, lack of incentives for adequate credit assessment and monitoring (because of the seemingly unlimited willingness of the government to bail out banks) and lack of legal enforcement of financial contracts, as well as general property-rights and transparency issues, lead to massive mis-allocation of savings (2/3 of savings are channeled to the public sector through the banking system) and to the accumulation of non-performing assets on banks' balance sheets (estimates of non-performing loans range from 20 to 50% of the largest banks' total loan portfolios, or 30 to 80 % of GDP; see van der Linden, 2005).

Based on conclusion 3 above: At least two more reasons for excess liquidity in the Chinese banking system exist. First, the financial system in general is underdeveloped and unable to absorb the large monetary overhang in the economy; i.e., there is a lack of alternative investments, especially for short-term funds (see money market structure, above). Second, there exist *de facto* lending restrictions. There is much to suggest that more or less official administrative control of the quantity and direction of banks' lending is currently the most important instrument at the PBC's disposal to contain money supply growth. At the same time, these practices are counter-productive to the longer-term interests of the PBC to improve the transmission mechanism to the extent that they leave banks awash with liquidity.

6. Conclusion

Up to the late 1970s and early 1980s, money markets (as well as the financial sectors in general) in our European case countries were typically underdeveloped and highly regulated. Since then, politics – through financial sector deregulation, government debt policy, and de-politicization of monetary policy – has been one of the main determinants of money-market development.

We argue that financial deregulation as an ‘active’ or ‘passive’ response of politicians to developments beyond their control, the need to find new and more flexible sources of government borrowing, and the need to establish a forum for effective monetary-policy implementation—go a long way to explain the significant cross-country differences among our European focus countries in terms of money-market size and structure, as well as the timing and direction of various policy decisions and outcomes. A main observation is also that a policy decision, once taken, cannot easily be reversed, as the development over time may be characterized as a continuous interplay between policy decisions and market outcomes. The development process thus becomes highly *path dependent*, and largely reflects political *ad-hoc* decisions, which are often, in themselves, responses to market developments. There are also considerable potential spill-over effects from other policy areas. Therefore, a gradualist approach and ‘controlled’ financial deregulation is difficult, because – from the point of view of the policy purpose – financial market regulations are complementary (doing away with one undermines the purpose of another), and – more generally – ‘controlled’ and ‘deregulated’ are in some sense mutually exclusive.

Chinese monetary policy is largely characterized by this type of spillover effects, and is full of inherent inconsistencies and conflicts of interest, giving rise to a large degree of discretionary, *ad hoc* policy measures. As a consequence, China will not be able to emulate other countries’ experiences, but outcomes will reflect exogenous factors affecting its policy and policy responses to those factors, if anything is to be learned from the European countries we study here, where central banks have often had a decisive influence on money-market development.

Some countries have changed the basic monetary-policy regime one or more times during the period studied (Finland, Greece, Portugal and Sweden are the most obvious examples, excepting the changeover to EMU). Changes in monetary-policy conditions and

operations are correspondingly big in these countries. Among the countries that essentially stuck to the same policy regime (exchange-rate targets, mostly) throughout the 1980–1998 period, some saw less dramatic changes in the indicators used to analyze monetary policy (Austria, Belgium), while in others, the changes were of average magnitude (Netherlands) or comparatively big (Denmark).

Did comparatively radical structural changes in the domestic money market (in terms of innovation, market growth and regulatory changes) correspond also to bigger changes in monetary policy? There seems to be *some* connection between, for instance, the size of short-term securities markets and the magnitude of change in monetary-policy operations: the limited market growth in Austria and Switzerland, for instance, goes together with small changes in central-bank operations; equally, the larger markets of Finland and Sweden fit with more and/or bigger changes in the operative aspects of monetary policy. On the other hand, the limited size of the short-term securities market in the Netherlands, for instance, does not seem to preclude significant changes in policy procedures. It must also be added that the gradually increased reliance on the part of central banks on indirect, market-based instruments for policy making is more or less a universal phenomenon. Moreover, and as already stressed, the development of markets in which to conduct open-market operations has in many cases been explicitly or implicitly supported by monetary authorities.

A few lessons for China from the European transition period directly related to the money market could be the following.

- A general recommendation and a clear lesson from the European experience is to focus objectives as well as operative targets of monetary policy.
- One part of this increased focus could be increased flexibility of the exchange rate: As explained above, whether the RMB is under-valued or not, the rigid exchange rate (the *de facto* effects of the modest revaluation and move to a ‘managed float’ in July 2005

remain to be seen) has undermined attempts so far to foment broader and deeper financial markets, not least a functioning money market, and is directly counter-productive to the effectiveness of the PBC's market operations. With the so-far rigid currency regime, the absence of adjustment to capital movements on the exchange rate effectively implies that adjustments are being 'passed on' to a domestic financial system which is not developed enough to handle it. A more flexible exchange rate would also stimulate the development of the foreign-exchange market, including a market for FX derivatives linked to the domestic money market.

- The banks' continued lack of *de facto* independence as economic entities is distorting the financial intermediation process as well as the PBC's own capacity for effectively implementing policy. For market operations to work, there must be a market of independent market participants acting on the basis of market criteria – i.e., the PBC must not be able to use its political clout to force the banks to respond to various measures when in fact they have no economic incentive to do so.
- Creation of short-to-medium term securities market based on *bank* liabilities, such as a CD market; this could help banks clean up their balance sheets (instead of piling up liquidity or channeling it into speculative fixed investments), as well as providing alternative investments to drain the money market of excess liquidity.
- Create a viable treasury bill (short-term government debt) market; with the present continued weakness of the banking system, it is unlikely that a CD market could function as a benchmark segment for the short end of the debt market.

It should be noted that many of these solutions rely on more broad-based institutional reforms to work properly. China is still largely a 'commando economy', which – whether that command is explicitly or implicitly exerted – eliminates the proper incentives to reach market

clearing outcomes in whatever market. Imbalances will persist without a firmer and more unconditional commitment to market principles.

Notes

¹ The cross-country studies that exist – for instance, Kneeshaw and Van den Bergh (1989), Batten *et al.* (1990), Bernanke and Mishkin (1992), Kasman (1992), Goodhart and Viñals (1994), Hooyman (1994), Bisignano (1996), Borio (1997), BIS (2001), Kopcke (2002) – consistently indicate that changes in the operative frameworks of central banks have been both effects and drivers of broader changes in the financial and monetary environment, but also suggest important differences across countries in these respects.

² Objectives, or targets, are often divided into intermediate and final targets. A fixed exchange rate, for instance, is mostly considered an intermediate target, price stability a final target. The central banks' own definitions of their targets or objectives, however, vary both over time and across countries.

³ For a more comprehensive account of the process of financial deregulation in the Nordic countries, see Oxelheim (1996); a recent survey of this process for a large number of countries, including many emerging-market countries, is provided in Williamson and Mahar (1998); beyond these, the best sources for specifics on deregulation in particular countries are usually publications from the central bank of the country in question. OECD's *Financial Market Trends* is also a useful source.

⁴ Retail interest rates were controlled in practice in Austria at least until the mid-1990s via gentlemen's agreements between banks; credit has also traditionally been heavily subsidized: in the early 1990s almost half of all credit extended to industry, though formally free from regulations, was subsidized (see Pech, 1994).

⁵ The usual argument given for this sequence of events is that agents in wholesale markets are assumed to be more professional, thus better qualified to handle market-determined rates; see, for example, Mehran *et al.* (1997).

⁶ Temporary regulations have been resorted to in extreme cases even in recent years. The latest example is the imposition by the Bank of Greece of a 12-percent credit-expansion ceiling on commercial banks in 1999 after consumer credit had expanded more than 30 percent *p.a.* in 1998 and 1999 (Bank of Greece, *Monetary Interim Report, 1999*).

⁷ See, for example, the survey in OECD (1989). It can be noted that the pendulum with regard to branching restrictions and market-entry regulation currently tends to swing back somewhat toward increasing regulation, the establishment of firewalls between different types of business within multiple-business financial institutions, etc. This might be interpreted as an expression of a requirement of minimum regulation to avoid moral hazard and/or adverse-selection problems and to ensure public confidence in the financial system.

⁸ *Banker* (1993). Also see the *Economist* (1992) and Warner (1993) for short background articles on the deregulation and privatization of Portuguese banks.

⁹ General references for this sub-section not cited elsewhere include BIS (1986, 1997a), and Aspetsberger (1996).

¹⁰ In Switzerland, for instance, the underdeveloped domestic money market, the unaccommodative attitude of the National Bank with regard to reserve imbalances (resulting from its long-standing reserves target—now abolished—) and the comparatively high cost of Lombard (overdraft) facilities led Swiss banks to hold reserves substantially in excess of those required under reserve requirements (Kasman, 1992).

¹¹ These problems are particularly relevant in emerging stages of money-market development; see, e.g., Mehran *et al.* (1996); Kneeshaw and Van den Bergh (1989).

¹² Several advantages are perceived with repos as an instrument for monetary policy relative to more orthodox cash instruments. One advantage is that they do not directly influence the underlying asset prices. A second main advantage is their flexibility: they break the link between the maturity of the asset and the transaction, and can essentially be tailored to suit prevailing liquidity conditions. Thirdly, because repo transactions are backed by (high-quality) collateral, the risk involved is typically very low. This also means that they convey relatively accurate information on the market's interest-rate expectations over the short term. Finally, repos are seen as appropriate for signaling the central bank's monetary-policy stance.

¹³ Nonetheless, the introduction of the common monetary-policy framework in the euro area in 1999 altered the use of short-term paper as collateral for central-bank operations quite substantially. In most EMU countries, the use of short-term paper (particularly t-bills) as collateral for the ECB's refinancing operations increased as compared to the pre-EMU collateralized transactions of the respective national central banks. In Belgium, Ireland and the Netherlands, the proportion remained largely unchanged, whereas in Portugal and Finland, it decreased. In Portugal, the decline in short-term paper as collateral refers primarily to t-bills, which decreased from initially very low levels (3 percent). In Finland, however, collateral paper mostly consisted of bank CDs, the use of which dropped from about 30 to 20 percent after the adoption of the common monetary-policy framework in the euro area. See Santillán *et al.* (2000).

¹⁴ As an illustration, Green (2005) reports that the mispricing by the market of a long-term government bond issue made underwriters unable to resell the bonds without incurring major losses, forcing the PBC to step in and buy a large portion of the issue – effectively amounting to central bank financing of the government.

¹⁵ By 1987, the National Bank's holdings of currency swap contracts amounted to approx. half of its foreign-currency assets, which in turn amounted (together with gold) to almost 90% of its total assets. Roughly that situation remained until 1998, when the National Bank began to broaden its arsenal of instruments (Banque Nationale Suisse, *Bulletin Trimestriel* 4, December, 1999). Also see Zurlinden (1996).

¹⁶ As financial integration between countries increase, the narrowing interest-rate differentials vis-à-vis other countries imply that even very small interest-rate movements can generate considerable cross-border capital flows, making exchange-rate or money-supply targets increasingly difficult to meet. Hence the increasing need for instruments which would enable the central bank to influence domestic short-term rates with greater flexibility and accuracy.

¹⁷ One potentially complicating factor here is that if we believe that the central bank's policy measures can in and of themselves give rise to 'innovations', we have an endogeneity problem of the 'exogenous' factors: the central bank influences these factors *indirectly* through its own actions.
